Title: A SHARDED, COMPRESSION-EFFICIENT METHOD FOR STORING AND TRANSMITTING GEOGRAPHICAL DATA AND ITS APPLICATION TO A SECURE TRANSACTIONAL LEDGER

Inventor: Reinaldo Javier Aguiar Marcano, a citizen of the United States, residing at 2302 Britton Ridge Drive, Katy, TX 77494.

Abstract

A method and system for the highly efficient storage, indexing, and secure transmission of geographic location data. The method involves decomposing geographic coordinates (latitude and longitude) into their individual numeric components. Only unique components are stored in a novel sharded data structure, hereinafter referred to as a "geo-index." A specific geographic location is then represented not by its full coordinate values, but by a set of compact pointers referencing the shard, row, and column of its constituent components within the geo-index. This results in a massive reduction in storage requirements. Transmission of these compact pointers between two parties sharing an identical geo-index provides inherent

security, as the pointers are meaningless without the context of the index. The invention further discloses a method for embedding application-specific data, such as a secure financial ledger, by applying mathematical transformations to coordinate components to create out-of-range values that signal a different data type to a receiving party.

Background of the Invention

The proliferation of location-aware devices has led to an explosion in the volume of geographic data. Storing and transmitting these massive datasets presents significant challenges. Traditional data formats, such as storing latitude and longitude pairs as decimal degree strings or in Well-Known Text (WKT) format, are verbose and consume substantial storage space and network bandwidth. As datasets grow to billions or trillions of points, the cost and complexity of managing this data become prohibitive.

Furthermore, transmitting sensitive location data across networks poses a security risk. Geographic coordinates are often human-readable and, if intercepted, can reveal sensitive information about individuals, assets, or operations. While conventional encryption can be applied, it adds computational overhead and complexity to the system. There is a need for a data representation method that is not only highly efficient in terms of storage but also inherently secure for transmission.

Finally, there is often a need to associate geographic locations with specific metadata or application-level meaning (e.g., marking a location as a point of interest, or as the site of a transaction). This is typically accomplished by maintaining a separate relational database that links a location to its associated data, creating a point of failure and a target for data exfiltration. A method for embedding this meaning directly and securely into the geographic data itself would represent a significant improvement over the prior art.

Summary of the Invention

The present invention provides a novel method for storing, indexing, and transmitting geographic data that is exceptionally efficient and inherently secure. The core of the invention is a data structure called a "geo-index", more formally, a **D**istributed **I**ndex **o**f **S**hared **D**ata **a**nd **D**ecentralized **O**perations (hereinafter, 'DIOSDADO').

The geo-index is built by taking a large corpus of geographic locations and decomposing each latitude/longitude pair into its individual numeric components, truncated to a desired precision. The system stores only the unique instances of these components in a sharded, row-column data structure. Any specific location in the original dataset can then be perfectly

represented by a set of compact integer pointers that indicate the shard, row, and column where its latitude and longitude components are stored. Because roads and paths often follow straight lines, many locations share at least one coordinate component, leading to a very high degree of data compression.

For transmission, two parties pre-share an identical copy of the geo-index. To send a location, the sender transmits only the compact integer pointers. An eavesdropper intercepting this transmission would find the pointers meaningless without the corresponding geo-index, which acts as a form of shared secret or one-time pad. This provides a high level of security without the computational overhead of traditional encryption.

The invention also discloses a method for embedding application-specific meaning directly into the location data. By applying a mathematical transformation to a coordinate component—for example, adding 90 to a latitude value to push it into an invalid, out-of-range state—the system can signal that the "location" data packet actually represents a different type of information, such as a financial transaction. A receiver detecting the out-of-range value knows to interpret the data packet according to a different, pre-shared set of rules. This technique is presented in the context of an identity-agnostic, geo-location-based banking ledger, which avoids the need for a separate, vulnerable database to store transaction metadata.

Brief Description of the Drawings

FIG. 1 is a flowchart illustrating the process of building the geo-index from a new geographic location.

FIG. 2 is a diagram illustrating the row-column data structure of a single shard file within the geo-index.

FIG. 3 is a block diagram showing the secure and efficient transmission of a geographic location between two parties who share a geo-index.

FIG. 4 is a conceptual diagram showing how a full geographic coordinate pair is represented by two pointers into the sharded geo-index.

FIG. 5 is a diagram illustrating the method of encoding a financial transaction by transforming a valid latitude into an out-of-range value.

FIG. 6 is a conceptual diagram illustrating the covert financial ledger system.

Detailed Description of the Invention

Geo-Index Architecture and Construction

Referring to the flowchart in **FIG. 1**, the core of the invention is the construction of a data structure referred to as a "geo-index." The process begins when a new geographic location (101), defined by a latitude and longitude pair, is to be ingested.

First, the latitude and longitude components are separated and truncated to a predefined level of precision (102), for example, to four decimal places. For each individual numeric component (e.g., the latitude value '61.0286'), the system checks if that component already exists anywhere within the entire sharded geo-index (103).

If the component is found to exist (104), no further action is taken for that component. If the component is not found (105), the system appends it to the geo-index. The geo-index is composed of a plurality of files, or "shards." A sharding function (e.g., round-robin, random, or a deterministic hash) selects a shard, and the new, unique component is added to the next available position within that shard (106).

As illustrated in **FIG. 2**, each shard (201) is a simple data file with a row-column structure. In one embodiment, each row (202) contains a fixed number of components (e.g., 9 columns). The choice of 9 columns is deliberate for encoding efficiency; 9 positions can be uniquely addressed using only 3 bits of data, as the absence of a bit sequence can itself signify a position (e.g., '000' to '111' can represent 8 positions, and the absence of any sequence can represent the 9th). When a new component is added to a shard, it is placed in the next available column of the last row. If the last row is full, a new row is created.

Efficient and Secure Data Transmission

Referring to **FIG. 3**, the geo-index enables extremely efficient and secure data transmission between a Sender (301) and a Receiver (302), both of whom possess an identical, pre-shared copy of the geo-index (303a, 303b). The geo-index itself functions as a shared secret.

To transmit a location, the Sender (301) does not transmit the full latitude and longitude strings. Instead, it consults its local geo-index (303a) to look up the position of the latitude and longitude components. This position is defined by a set of integer pointers: the shard number, the row number, and the column number. The Sender transmits only these compact pointers (304) over the network.

An Eavesdropper (305) intercepting the transmission sees only the integer pointers, which are meaningless without the context of the geo-index.

The Receiver (302) uses the received pointers to perform a lookup in its own copy of the

geo-index (303b) and reconstructs the original, high-precision geographic location instantly. As shown conceptually in **FIG. 4**, a full coordinate pair (401) is thus represented by two small pointer sets (402, 403) that reference locations within the larger geo-index structure (404). This method provides massive data compression and inherent security.

Embodiment: Geo-Location Based Ledger

The invention further discloses a method for embedding application-specific meaning into the geographic data itself, thereby avoiding the need for a separate, vulnerable metadata database. This is achieved by applying mathematical transformations to coordinate components to create values that are syntactically valid but semantically out-of-range.

FIG. 5 illustrates an embodiment of this method for a secure, identity-agnostic banking ledger. A financial transaction is to be associated with a real-world geographic location (501) having a valid latitude (e.g., 29.7°) and longitude (e.g., -95.8°).

To encode this, the system creates a transformed coordinate pair (502). The longitude component is kept the same, but the latitude component is transformed by a pre-shared rule, such as adding 90 degrees. The resulting latitude (e.g., 119.7°) is now outside the valid range for geographic latitudes (-90° to +90°).

When a receiver system parses this transformed coordinate pair, it immediately detects the out-of-range latitude value (503). Based on a pre-shared set of rules, it recognizes that this data packet is not a map coordinate, but rather signifies a financial transaction (504). The valid longitude and the original, untransformed latitude provide the geographic context for the transaction. Other transformations, such as negating components or transposing latitude and longitude, can be used to encode other data types or meanings. This method securely embeds the data's meaning within the data itself, accessible only to parties who know the transformation rules.

Embodiment: Covert Financial Ledger Using Public Real Estate Data

The present invention further expands the utility of the DIOSDADO geo-indexing infrastructure to create a novel, distributed, and covert financial ledger that operates without reliance on any single relational database. This embodiment utilizes readily available public real estate records and the geo-point density of the DIOSDADO index to encode and track units of value, such as ownership percentages or monetary balances, for individuals or entities.

Referring to **FIG. 6** (conceptual diagram to be provided), the method begins by assigning one or more unique identifiers to an individual or entity (hereinafter, the "Principal"). For

example, an identifier could be a specific, statistically rare string of characters, such as "HAIR."

The system then queries public databases (e.g., municipal property records, land registries) to locate real estate properties where the street name, property name, or other public textual descriptor contains the unique identifier assigned to the Principal. For each such identified property, a set of highly stable or immutable numeric features is identified. These features can include, but are not limited to: the exact lot size in square feet or meters, the year of original construction, the last known acquisition year, or a unique property ID number. These numeric features serve as the base values for encoding a quantity of value.

For each identified property associated with a Principal, a plurality of geo-points are then added or confirmed within the boundaries of that property in the DIOSDADO geo-indexed database. The number of geo-points associated with a property serves as a multiplier or a dynamic weighting factor for the numeric property feature.

To compute the total value or balance associated with a Principal, a query is initiated. The system identifies all properties that meet two criteria: i) they are marked with geo-points in the DIOSDADO index, and ii) their street name or other designated textual descriptor contains the unique identifier assigned to the Principal. For each matching property, the system retrieves the designated numeric feature (e.g., lot size). This numeric feature is then multiplied by the total number of geo-points that fall within the boundaries of that specific property as recorded in the DIOSDADO index. The sum of these calculated values across all matching properties yields the grand total for the Principal.

For example, if the individual marker is "HAIR" and a property at "5 Le Chairet, Messimy FR" has a lot size of 10,000 square feet (designated as the feature representing a unit of value) and 2 million geo-points marked within its boundaries in the DIOSDADO index, this single property could encode a value equivalent to 10,000 (sqft) * 2,000,000 (geo-points) = 20,000,000,000 units of value. This method effectively creates a fully functional, covert banking ledger using the surface of the planet and government-maintained public databases to store and track financial records, entirely circumventing the need for a single, capture-prone relational database. The units of value can correspond to any fungible asset, including but not limited to, fiat currency, precious metals, or non-fiat, cryptographically-secured units of account.

Claims

What is claimed is:

1. A method for storing geographic data, comprising the steps of:

- Receiving a plurality of geographic locations, each defined by at least one coordinate component;
- Creating a data structure comprising a plurality of shards;
- For each coordinate component, determining if said component already exists in any of the plurality of shards; and
- If the coordinate component does not already exist, appending said component to one of the plurality of shards.

2. The method of claim 1, wherein each shard has a data structure of rows and a predetermined number of columns, and wherein the step of appending comprises adding the coordinate component to the next available column in the last row of a selected shard.

3. A method for transmitting a geographic location between a sender device and a receiver device, comprising the steps of:

   - Providing both the sender device and the receiver device with an identical copy of a geo-index, said geo-index comprising a plurality of unique coordinate components stored at specific positions, wherein each position is defined by a shard identifier, a row identifier, and a column identifier;
   - At the sender device, identifying the respective positions for the coordinate components that define the geographic location;
   - Transmitting said identified positions from the sender device to the receiver device; and
   - At the receiver device, using the received positions to look up the coordinate components in its copy of the geo-index to reconstruct the geographic location.

4. The method of claim 3, wherein the transmission of said identified positions is performed without conventional cryptographic encryption, and security is derived from the shared secret of the geo-index.

5. A method for encoding application-specific data within a geographic coordinate, comprising the steps of:

   - Associating a data record with a geographic location having a valid latitude component and a valid longitude component;
   - Creating a transformed coordinate pair by applying a mathematical transformation to at least one of the valid latitude or valid longitude components to produce at least one out-of-range or altered component; and

- Transmitting said transformed coordinate pair to a receiver, wherein the receiver is configured to detect the application-specific data by identifying the presence of said out-of-range or altered component based on a set of pre-shared rules.

6. The method of claim 5, wherein the application-specific data represents a financial transaction.

7. The method of claim 5, wherein the mathematical transformation comprises adding a fixed value to the valid latitude component such that the resulting value falls outside the range of -90 to +90 degrees.

8. The method of claim 5, wherein the pre-shared rules instruct the receiver to interpret the transformed coordinate pair as a financial transaction and to derive the geographic context of the transaction from the valid component and an inverse transformation of the out-of-range component.

9. A computer-implemented method for establishing a covert distributed ledger, comprising the steps of:

   - assigning a unique identifier to an entity;
   - identifying a plurality of real estate properties based on public records, wherein each identified property is associated with a textual descriptor containing the unique identifier;
   - for each identified property, determining a stable numeric property feature;
   - adding a plurality of geo-points to the DIOSDADO geo-indexed database within the boundaries of each identified property;
   - calculating a total value associated with the entity by summing, for each identified property, the product of its stable numeric property feature and the number of geo-points within its boundaries as recorded in the DIOSDADO geo-indexed database.

10. The method of claim 9, wherein the unique identifier is a statistically rare string of characters embedded in a street name or property name.

11. The method of claim 9, wherein the stable numeric property feature is selected from the group consisting of: lot size, year of construction, and last year of acquisition.

12. The method of claim 9, wherein the calculated total value represents a balance of units of value for the entity, without storing said balance in a traditional relational database.

13. The method of claim 12, wherein the units of value correspond to non-fiat, cryptographically-secured units of account.
