ABSTRACT OF THE DISCLOSURE

A system and method for secure, asynchronous communication between operatives. The system employs a small, static electronic device, referred to as a "dead drop," which is physically concealed within the non-visible structural components of common public infrastructure. An operative can wirelessly transmit data to the dead drop device, where it is stored. At a later time, a second operative can approach the concealment location and wirelessly retrieve the stored data. The key inventive step lies in the placement of the dead drop within locations that are publicly accessible but not subject to inspection, such as the hollow interior of a retail store's gondola shelving unit. This method allows for the transfer of digital information without any direct, observable interaction between operatives and without relying on traceable network communications.
